

Coffee Sales Performance Dashboard

A Power BI project turning raw coffee sales data into a clear, interactive story

Why I built this

I wanted a hands-on way to practice turning messy, real-world sales data into something a business owner could actually use to make decisions. I picked a coffee sales dataset covering orders from the US, UK, and Ireland, and set out to build a dashboard that would answer the questions a sales manager would ask on a Monday morning: How are we doing overall? Where are our sales coming from? What's selling best?

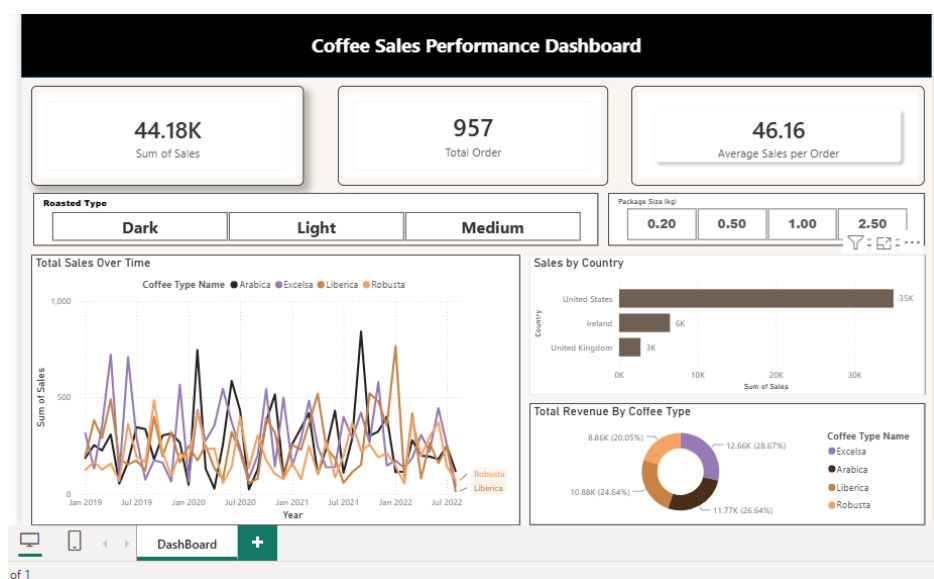

The starting point

The data came in three separate spreadsheets: one with order details, one with customer information, and one with product details like coffee type, roast, and size. None of it was connected, and some of the fields (like coffee type and roast level) were stored as short codes rather than readable labels. Before I could build anything, I needed to clean this up and connect the pieces.

What I did

- Linked the three data tables together using shared ID fields, so an order could be traced back to the right customer and the right product.
- Wrote simple formulas to turn coded fields into plain labels, so 'Ara' became 'Arabica' and 'D' became 'Dark Roast', for example.
- Built three summary cards at the top of the dashboard for total sales, total orders, and average order value, so anyone opening the report gets the headline numbers immediately.
- Added filters for roast type and package size, so a user can narrow the whole dashboard down to just the products they care about, without touching any of the underlying data.
- Created a chart tracking sales over time by coffee type, a bar chart showing which countries sell the most, and a donut chart showing how revenue splits across coffee types.

What the dashboard shows

44.18K Total Sales	957 Total Orders	46.16 Average Sale per Order
------------------------------	----------------------------	--

What I found

The United States accounts for the large majority of sales, well ahead of Ireland and the UK, which suggests that's where the strongest customer base is. Looking at revenue by coffee type, the split is fairly even across the four types, with Liberica and Robusta together making up around half of total revenue. The sales-over-time chart also makes it easy to spot which coffee types have the most volatile demand versus which sell more steadily month to month.

What I learned

This project was as much about the groundwork as it was about the final dashboard. Getting three unrelated spreadsheets to work together taught me a lot about how important a clean, well-connected data structure is before any chart or number means anything. It also pushed me to think about the dashboard from the reader's point of view: what do they need to see first, and what should they be able to filter on their own without asking me for a new version.

Tools used

Power BI, Power Query, DAX, and Excel.
